The aim of our research program is to develop highly selective sensory tags for odorants that are based on cyclodextrins and their derivatives. These tags will be useful in chemical analyses, such as chemosensing in vivo, and in the isolation and purification of odorous compounds. In Phase I, we will develop a highly selective chemical sensor based on the CD-host complexation of the acetophenone chromophore, and will demonstrate its ability to distinguish between the odorants acetophenone and benzaldehyde. We will synthesize a series of substituted cyclodextrins and test their ability to form complexes with acetophenone. Finally, we will test the ability of a series of substituted CDs to form complexes with benzaldehyde. The goal of Phase II is to develop an instrument that will utilize the versatile CD-chromophore technology described in this proposal to develop inexpensive, robust, and selective chemical sensors for the detection of organic compounds, such as in situ odorants in compost, explosives, and drugs in air, water, and soil. The specific aims of Phase II are: 1) To synthesize a series of cyclodextrins and their derivatives, chemically modified with alkyl chains, in order to enhance the solubility of acetophenone, but not affect the complexation properties of CDs; 2) To
